51 **Abstract:**

52

53 **Purpose:** To compare the effects of test protocols with different increments in workload and duration on peak  
54 oxygen uptake ( $\dot{V}O_{2peak}$ ), and related physiological parameters during seated upper-body poling (UBP). **Methods:**  
55 Thirteen upper-body trained, male individuals completed four UBP test protocols with increments in workload  
56 until volitional exhaustion in a counterbalanced order: 20W increase/every 30s, 20W/60s, 10W/30s and 10W/60s.  
57 Cardio-respiratory parameters and power output were measured throughout the duration of each test. Peak blood  
58 lactate concentration ( $bLa_{peak}$ ) was measured after each test. **Results:** The mixed model analysis revealed no  
59 overall effect of test protocol on  $\dot{V}O_{2peak}$ , peak minute ventilation ( $VE_{peak}$ ), peak heart rate ( $HR_{peak}$ ),  $bLa_{peak}$ , (all  $p$   
60  $\geq 0.350$ ), whereas an overall effect of test protocol was found on peak power output ( $PO_{peak}$ ), ( $p=0.0001$ ),  
61 respiratory exchange ratio (RER) ( $p=0.024$ ) and test duration ( $p<0.001$ ). There was no difference in  $PO_{peak}$  between  
62 the 20W/60s ( $175\pm 25W$ ) and 10W/30s test ( $169\pm 27W$ ;  $p=0.092$ ), whereas  $PO_{peak}$  was lower in the 10W/60s test  
63 ( $152\pm 21W$ ) and higher in the 20W/30s test ( $189\pm 30W$ ) compared to the other tests, (all  $p=0.001$ ). In addition,  
64 RER was 9.9% higher in the 20W/30s- compared to the 10W/60s test protocol, ( $p=0.003$ ). **Conclusions:** The UBP  
65 test protocols with different increments in workload and duration did not influence  $\dot{V}O_{2peak}$  and can therefore be  
66 used interchangeably when  $\dot{V}O_{2peak}$  is the primary outcome. However,  $PO_{peak}$  and RER depend upon the test  
67 protocol applied and the UBP test protocols can therefore not be used interchangeably when the latter are primary  
68 outcome parameters.

70

71 **Abbreviations**

72 ACE – arm-crank ergometry

73  $bLa_{peak}$  – peak blood lactate

74  $HR_{peak}$  – peak heart rate

75  $PO_{peak}$  – peak power output

76 RER – respiratory exchange ratio

77 RPE – ratings of perceived exertion

78 UBP- upper-body poling

79  $\dot{V}CO_2$  – carbon dioxide production

80 VE – minute ventilation

81  $\dot{V}O_{2peak}$  – peak oxygen uptake

82 W – watt

## 132 Introduction

133  
134 Testing peak oxygen uptake ( $\dot{V}O_{2\text{peak}}$ ) and associated cardiorespiratory parameters during upper-body exercise is  
135 relevant for determining endurance capacity in individuals with an impairment of the lower extremities and in  
136 able-bodied athletes involved in sports where upper-body exercise contributes to overall performance. The exercise  
137 modalities most commonly used in a clinical- and sport setting are arm-crank ergometry (ACE) and wheelchair  
138 ergometry (Gauthier et al. 2017b; Goosey-Tolfrey et al. 2006; Pelletier et al. 2013). However, in a sports context,  
139 specificity of the test mode is important for attaining a  $\dot{V}O_{2\text{peak}}$  that is reflective of the endurance capacity in the  
140 respective sport. For example, in Para ice hockey, Para cross-country sit skiing and Para biathlon, testing  $\dot{V}O_{2\text{peak}}$   
141 in the upper-body poling (UBP) mode may be a more sport-specific alternative compared to the ACE or wheelchair  
142 ergometer mode. Furthermore, the reliability of seated UBP for testing  $\dot{V}O_{2\text{peak}}$  has been established while  
143 employing different incremental and all-out closed-ended test protocols in able-bodied cross-country skiers  
144 (Baumgart et al. 2017).

145  
146 So far, studies using the ACE or wheelchair ergometer mode have employed exercise test protocols with different  
147 increments in speed (e.g. 0.1-0.6 m/s), slope (e.g. 2.7-4.8°) or resistance (e.g. 6-25 W) (Bar-Or and Zwiren 1975;  
148 Bhambhani et al. 1991; Gauthier et al. 2017b; Hutchinson et al. 2017; Leicht et al. 2009; Leicht et al. 2013; Price  
149 and Campbell 1997; Sawka et al. 1983; Smith et al. 2001) every 1 or 2 min. However, only few of the studies  
150 investigated the direct effect of different incremental protocols on the values of  $\dot{V}O_{2\text{peak}}$  and peak power output  
151 ( $PO_{\text{peak}}$ ) during upper-body exercise. In one study, Washburn and Seals (1983) compared continuous (increasing  
152 PO every 1 min) and discontinuous ( increasing PO every 2 min separated by 1 min rest) ACE protocols and found  
153 no difference in  $\dot{V}O_{2\text{peak}}$ . In ACE protocols matched for workload, Smith et al. (2004) found no difference in  
154  $\dot{V}O_{2\text{peak}}$  between step-wise and ramp incremental protocols (20 W increase every 2 min vs 1 W/6 s, respectively).  
155 Furthermore, in ACE protocols matched for increment duration, no difference in  $\dot{V}O_{2\text{peak}}$  was found between high-  
156 versus low-workload increment protocols (12 W/min vs. 6 W/min, respectively (Smith et al. 2006), and 2 W/6 s  
157 vs 1 W/6 s, respectively (Castro et al. 2010). However, in the latter two studies,  $PO_{\text{peak}}$  was significantly higher in  
158 the test protocols with higher increments in workload compared to the test with lower increments in workload.

159  
160 Studies employing test protocols in an upper-body exercise mode apply different criteria for stopping a peak test  
161 and/or determination of  $\dot{V}O_{2\text{peak}}$ . The most common criteria for stopping a test are the inability to maintain a crank-  
162 rate at or above 40-80 revolutions per minute (Castro et al. 2010; Hutchinson et al. 2017; Pelletier et al. 2013;  
163 Smith et al. 2006; Smith et al. 2004; Smith et al. 2001; Washburn and Seals 1983), the inability to maintain a  
164 certain PO. In addition, common criteria for determining that  $\dot{V}O_{2\text{peak}}$  has been reached are an achievement of >  
165 80% of age predicted maximal HR and an RPE of > 17 (Leicht et al. 2009; Walker et al. 1986), a respiratory  
166 exchange ratio (RER) > 1.1 or a plateau in  $\dot{V}O_2$  (change < 2.1 mL/kg/min) (Gauthier et al. 2017a) and reaching  
167 volitional exhaustion (Price and Campbell 1997). Methodological diversity in the abovementioned criteria may  
168 influence the validity of a “true”  $\dot{V}O_{2\text{peak}}$  and make comparisons between studies difficult. Furthermore, for the  
169 studies that stop at the inability to maintain a certain PO, it remains unknown whether the  $\dot{V}O_2$  at  $PO_{\text{peak}}$  is a valid  
170 value of  $\dot{V}O_{2\text{peak}}$ .

172 Whether test protocols with different combinations of workload and duration ~~duration and workload~~ increments  
173 influence  $\dot{V}O_{2peak}$  and  $PO_{peak}$  in the seated UBP mode has not yet been investigated. Therefore, the primary aim of  
174 the present study was to compare  $\dot{V}O_{2peak}$  and  $PO_{peak}$  during seated upper-body poling between the following  
175 incremental protocols until volitional exhaustion: 20 W increase every 30 s, 20 W/60 s, 10 W/30 s and 10 W/60 s.  
176 Unpublished observations made in our laboratory during UBP testing of both able-bodied and individuals with a  
177 spinal cord injury in the study of Baumgart et al. (2018) revealed an increase in  $\dot{V}O_2$  despite a drop in PO.  
178 Therefore, the secondary aim was to investigate whether the  $\dot{V}O_2$  value at the time-point where  $PO_{peak}$  was obtained  
179 differed from the  $\dot{V}O_{2peak}$  value at the time point where the test was ended. Based on previous findings from studies  
180 using the ACE mode, our primary hypothesis was that no difference in  $\dot{V}O_{2peak}$  would be found between the four  
181 test protocols and  $PO_{peak}$  would be highest in the protocol with the high workload-short duration increment (20  
182 W/30 s) compared to the low workload-long duration increment (10 W/60 s). Our secondary hypothesis was that  
183 the value of  $\dot{V}O_2$  at  $PO_{peak}$  would be lower compared to the value of  $\dot{V}O_{2peak}$ .

184

## 185 **Method**

186

### 187 **Participants**

188 Thirteen, able-bodied male upper-body trained individuals (age  $28.6 \pm 3.3$  years; body-mass  $83.7 \pm 11.9$  kg; height  
189  $183.1 \pm 5.1$  cm), recruited from a list of former athletes in cross-country skiing at the Centre for Elite Sports  
190 Research, NTNU volunteered to participate in this study. The participants were familiar with upper-body poling  
191 from training cross-country skiing, approximately 2-3 times per week. The study was approved by the Norwegian  
192 Centre for Research Data (ID 51228) and conducted in accordance with the declaration of Helsinki. All participants  
193 signed an informed consent prior to inclusion and were made aware of the possibility to withdraw from the study  
194 at any point in time.

195

### 196 **Design**

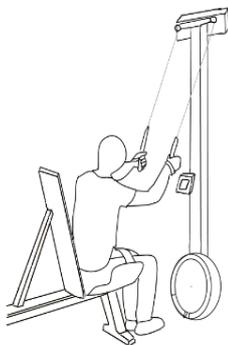

197 A repeated measures design was used, where four incremental UBP test protocols were performed in a  
198 counterbalanced order: 20 W increase every 30 s, 20 W/60 s, 10 W/30 s and 10 W/60 s. The four test protocols  
199 were completed within a two-week period with a minimum of 48 hours between each test day. The tests were  
200 performed at approximately the same time of day to avoid variation between tests induced by diurnal fluctuations  
201 (Reilly et al. 2007).

202

### 203 **Test set-up**

204 Participants were instructed to refrain from heavy exercise and alcohol consumption 24 hours prior to, caffeine  
205 intake the day of and food intake 2 hours before testing. Body-mass and height were measured before testing on  
206 day one. Standardised instructions on the use of the BORG (6-20) scale for rating of perceived exertion (RPE)  
207 were given (Borg 1982). Participants were fitted with a short-range telemetric heart rate monitor (M400 Polar  
208 Electro Inc., Port Washington, NY, USA) and a mouthpiece and a nose clip (Hans Rudolph Inc., Kansas City, MO,  
209 USA). Furthermore, they tightly strapped themselves around the hips and thighs into a seat construction in front  
210 of the Concept2 ski-ergometer (Concept2, Inc., Morrisville, USA) (Figure 1). The seat construction (a modified  
211 weightlifting bench) was placed in front of the ski-ergometer to allow for simultaneous elbow extension, trunk and  
212 shoulder flexion during UBP. Participants performed a 3-min bout of UBP at RPE 9 to familiarise with the seated

213 poling technique and to ensure proper seating. All had previous experience with cardiorespiratory measurements  
214 during double poling on the ski ergometer. Prior to testing, the participants were informed about the specific test  
215 protocol that was performed that day. Cardiorespiratory parameters were measured using open-circuit calorimetry,  
216 with expired gases passing through the mixing chamber of the Jaeger ergospirometer (Oxycon Pro, Jaeger, Viasys  
217 BV, Biltoven, The Netherlands) which has previously been validated against the Douglas-bag technique (Foss  
218 and Hallén 2005). Before the tests, the ergospirometer was calibrated against a set mixture of gases (5% CO<sub>2</sub>, 15%  
219 O<sub>2</sub>) and against ambient air. The flow volume transducer was calibrated automatically. Average values were  
220 recorded in 10 s intervals. Power output (PO) per stroke was recorded by the ski-ergometer's internal software  
221 (Concept2, Morrisville, USA). An ErgStick (Endurance Sports Research Limited, United Kingdom) was  
222 connected to the PM4 monitor of the Concept2 ski ergometer and the application Float (ErgStick Ltd, United  
223 Kingdom) used to retrieve the raw data. In addition, a digital camera (Sony alpha a58, Sony Electronics Inc., San  
224 Diego, USA) was used as back up to record PO and stroke rate on the PM4 monitor.  
225

226  
227 Figure 1. Test set-up with the participant seated in front of the Concept2 SkiErg.

228  
229

### 230 **Test protocol and measurements**

231 After the three-minute familiarization period with the test set-up, a warm-up period was performed on the UBP  
232 ergometer, consisting of four 4-min submaximal stages at RPE 9 (very light), 11 (light), 13 (somewhat hard) and  
233 15 (hard). On the first test day, participants were instructed to exercise according to the target RPE to determine  
234 the workload for each submaximal stage. The individual's average PO from each submaximal stage was then used  
235 during the 4-min submaximal stages on the remaining three test days. After a 5-min passive rest period, a 3-min  
236 active recovery at RPE 9 was completed to remove the accumulated blood lactate (bLa) from the submaximal  
237 stages. The incremental test started at the individual PO from the RPE 11 stage (rounded to the nearest 5 W value)  
238 and was increased according to the specific test protocol for that day (either 20 W/30 s, 20 W/60 s, 10 W/30 s or  
239 10 W/60 s). The aim of starting at individual PO's from RPE 11, was to ensure that participants started at  
240 approximately the same relative intensity as well as to target similar test times within the test protocols. Stroke  
241 rate during all four tests was self-chosen and participants were instructed to continue poling despite not being able  
242 to maintain the desired PO for the specific increment as long as  $\dot{V}O_2$  continued to increase. The tests were  
243 terminated, when – despite verbal encouragement –  $\dot{V}O_2$  either plateaued (three values with  $< 2.0 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$

244 <sup>1</sup> difference) or dropped by  $> 2.0 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ . We argue that a plateau or drop in  $\dot{V}\text{O}_2$  are a valid way of  
245 knowing that a “true”  $\dot{V}\text{O}_{2\text{peak}}$  was attained. The criterion of a drop is not abundant in exercise testing since tests  
246 are usually stopped when speed/incline/power output/etc cannot be maintained.

247

248 PO and stroke rate wereas interpolated at 1-s intervals in Matlab (R2016a; Mathworks Inc., Natick, MA). 30-s  
249 moving averages were calculated for PO and cardiorespiratory parameters and the highest values defined as peak  
250 values. In addition to  $\text{PO}_{\text{peak}}$ , total work done (TWD) in kilojoules (kJ) until  $\text{PO}_{\text{peak}}$  was reached, was calculated as  
251  $\text{TWD (kJ)} = \sum_{i=1s}^s \text{at } \text{PO}_{\text{peak}}$  instantaneous  $\text{PO(W)} \cdot 1\text{s}/1000$ . HR was recorded every second and  $\text{HR}_{\text{peak}}$  was  
252 determined as the highest value of 3-s moving averages.

253

254 One and 3-min after each incremental test, a 20- $\mu\text{L}$  capillary blood sample was drawn from the fingertip and bLa  
255 was analysed with the Biosen C-Line Sport lactate measurement system (EKF-diagnostic GmbH, Magdeburg,  
256 Germany). The higher of the two bLa values was defined as  $\text{bLa}_{\text{peak}}$ . Furthermore, RPE using the BORG scale,  
257 was recorded after each test as described by Shepard et al. (1992).

258

259

## 260 **Statistical analysis**

261 Statistical analyses were performed in SPSS version 24 (IBM Corporation, Armonk, NY, USA). Descriptive data  
262 are presented as mean  $\pm$  SD and an  $\alpha$ -level of 0.05 was used to indicate statistical significance. A mixed model  
263 analysis with a fixed coefficient and random intercept was used to investigate the overall effect of the incremental  
264 test protocol on peak cardiorespiratory parameters,  $\text{bLa}_{\text{peak}}$  and  $\text{PO}_{\text{peak}}$ , TWD (kJ) until  $\text{PO}_{\text{peak}}$  and stroke rate.  
265 Linear mixed model analyses as opposed to repeated-measures ANOVA were employed since we had missing  
266 data for some variables. A Friedman test was used to investigate the overall effect of the increment test protocol  
267 on the categorical variable, RPE. Post hoc tests without adjustment (LSD) were performed for pair-wise  
268 comparisons between the four test protocols. Normality of residuals was checked with the Shapiro-Wilk test. For  
269 the secondary aim a mixed model analysis was also used to investigate the overall difference between  $\dot{V}\text{O}_2$  at  
270  $\text{PO}_{\text{peak}}$  and  $\dot{V}\text{O}_{2\text{peak}}$  while adjusting for the differences between test protocols. Post hoc tests without adjustment  
271 (LSD) were performed for pair-wise comparisons between  $\dot{V}\text{O}_2$  at  $\text{PO}_{\text{peak}}$  and  $\dot{V}\text{O}_{2\text{peak}}$  within each test protocol

272

273

## 274 **Results**

275 An overview of the mean  $\pm$  SD peak cardiorespiratory,  $\text{PO}_{\text{peak}}$ ,  $\text{bLa}_{\text{peak}}$ , perceptual parameters and test duration are  
276 presented in Table 1. Time to exhaustion was shortest in the higher workload-shorter increment-duration test (20  
277 W/30 s) (shorter duration test) and longest in the lower workload-longer increment-duration test (10 W/60 s)  
278 (longer duration test) (all comparisons  $p < 0.001$ ). No difference in time to exhaustion was found between the 10  
279 W/30 s and 20 W/60 s test protocols, ( $p=0.947$ ) (moderate duration tests). Despite the differences in total test  
280 duration, no overall effect of test protocol was found on  $\dot{V}\text{O}_{2\text{peak}}$  ( $p=0.813$ ),  $\text{HR}_{\text{peak}}$  ( $p=0.413$ ),  $\text{bLa}_{\text{peak}}$  ( $p=0.679$ ),  
281  $\text{VE}_{\text{peak}}$  ( $p=0.350$ ), RPE ( $p=0.486$ ) or stroke rate ( $p=0.097$ ). A plateau in  $\dot{V}\text{O}_2$  (three values with  $< 2.0 \text{ mL}\cdot\text{kg}^{-1}$   
282  $\cdot\text{min}^{-1}$  difference) or a drop by  $> 2.0 \text{ mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$  was observed for all the participants tested. There was an  
283 overall significant effect of test protocol on  $\text{PO}_{\text{peak}}$  ( $p < 0.001$ ). , TWD(kJ) ( $p < 0.001$ ),  $\text{RER}_{\text{peak}}$  ( $p=0.024$ ) and a

284 trend towards an effect on  $\dot{V}CO_{2peak}$  ( $p=0.060$ ). Pairwise comparisons revealed that  $PO_{peak}$  was highest in the test  
 285 of overall shorter duration (20 W/30 s) and lowest in the test of longer duration (10 W/60 s) (all comparisons  
 286  $p=0.001$ ), whereas no difference in  $PO_{peak}$  was found between the tests of moderate duration (20 W/60 s vs. 10  
 287 W/30 s), ( $p=0.092$ ). RER was higher in the shorter duration (20 W/30 s) and one of the moderate duration test  
 288 protocols (20 W/60 s) compared to the longer duration test protocol (10 W/60 s), ( $p=0.003$  and  $p=0.038$ ,  
 289 respectively). An overall lower  $\dot{V}O_2$  at  $PO_{peak}$  was found compared to  $\dot{V}O_{2peak}$  across test protocols ( $p<0.001$ )  
 290 (Figure 2). Compared to the  $\dot{V}O_{2peak}$  values, the values of  $\dot{V}O_2$  at  $PO_{peak}$  was 10.4% lower in the shorter duration  
 291 test ( $32.8 \pm 5.8$  vs.  $36.2 \pm 5.6$ ,  $p = 0.005$ ), 7.4 % ( $35.1 \pm 5.0$  vs.  $37.7 \pm 5.3$ ,  $p=0.006$ ) and 9.1% ( $35.3 \pm 4.5$  vs.  $38.5$   
 292  $\pm 5.1$ ,  $p=0.001$ ) lower in the moderate duration tests and 9.4% ( $37.2 \pm 6.6$  vs.  $40.7 \pm 5.9$  mL·kg<sup>-1</sup>·min<sup>-1</sup>,  $p=0.011$ )  
 293 lower in the longer duration test. Due to technical problems with the application Float, data for some of the PO  
 294 values over time went missing for some of the participants. This influenced the power of our results and the values  
 295 for  $\dot{V}O_2$  at  $PO_{peak}$  used in figure 2.

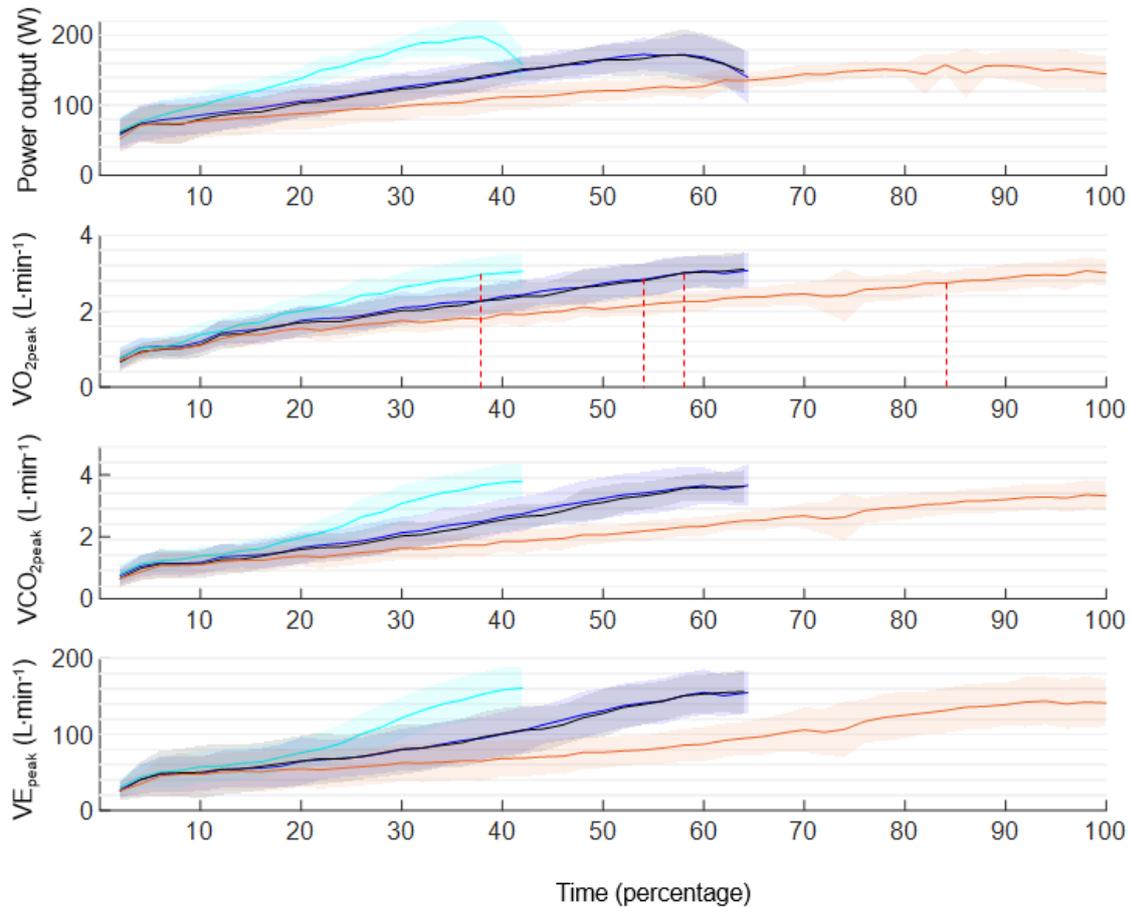

296

322 standard deviation for the four incremental tests.  $\dot{V}O_{2peak}$ =peak oxygen uptake,  
 323  $\dot{V}E_{peak}$ =peak ventilation, RER=respiratory exchange ratio,  $HR_{peak}$ =peak heart rate, RPE=ratings  
 324 of perceived exertion.  $bLa_{peak}$ =peak blood lactate. Significant differences at an  $\alpha$ -level of 0.05 were  
 325 determined between test 1 & 2:<sup>#</sup>, 1 & 3:<sup>\*\*</sup>, 1 & 4:<sup>§</sup>, 2&4:<sup>†</sup> and 3 & 4:<sup>\*</sup>  
 326 Note: For Test 4 (10W/60s), data of one participant on all variables was missing. Additionally, data for  
 327  $\dot{V}O_2$  at  $PO_{peak}$  was missing from 3-5 participants for the four test protocols due to a lack of continuous  
 328 PO data.

329

330 **Figure 2.** Power output,  $\dot{V}O_2$ ,  $\dot{V}CO_2$  and VE for the four test protocols in 13 male upper-body trained participants.  
 331 On the x-axis time is given as percent. Light blue line: protocol with 20W increase every 30s, blue line: 20W/60s,  
 332 dark grey line: 10W/30s and; light brown line: 10W/60s. Red dotted lines indicate  $\dot{V}O_2$  at  $PO_{peak}$  for the four  
 333 incremental test protocols. Participants were able to keep upper-body poling for 56 s, 1min 12 s, 56 s and 1min 22  
 334 s after reaching  $PO_{peak}$ , respectively.  
 335

336

### 337 Discussion

338

339 The aim of the present study was to compare  $\dot{V}O_{2peak}$ , related cardiorespiratory parameters and  $PO_{peak}$  between the  
 340 following upper-body poling test protocols with incremental workloads to exhaustion: 20 W/30 s, 20 W/60 s, 10  
 341 W/30 s and 10 W/60 s. In line with our hypothesis, no overall effect of test protocol on  $\dot{V}O_{2peak}$ ,  $VE_{peak}$ ,  $HR_{peak}$  and  
 342  $bLa_{peak}$  was found, indicating that they can be used interchangeably when these parameters are of interest. In  
 343 contrast,  $PO_{peak}$  was significantly higher in the test protocol of shorter duration (20 W/30 s) compared to the test  
 344 protocols of moderate duration (20 W/60 s and 10 W/30 s) and longer duration (10 W/60 s). Additionally, the  
 345 cardiorespiratory parameters  $RER_{peak}$  and  $\dot{V}CO_{2peak}$  were higher in the test of shorter duration (20 W/30 s)  
 346 compared to one test of moderate (10 W/30 s) and the longer duration test (10 W/60 s). In line with our secondary  
 347 hypothesis, the  $\dot{V}O_2$  at  $PO_{peak}$  was lower compared to the  $\dot{V}O_{2peak}$  value within all test protocols.  
 348

349 This is the first study to examine the influence of test protocols with different increments in workload and duration  
 350 on the peak physiological responses during seated UBP. The finding that  $\dot{V}O_{2peak}$  was not different between the

351 four protocols indicates that they tax the cardiorespiratory system equally. This is supported by no effect of test  
352 protocol on  $HR_{peak}$ ,  $VE_{peak}$  and RPE.  $PO_{peak}$  was, however, 24% higher in the shorter-duration protocol and 15%  
353 and 11.2% higher in the two moderate- compared to the longer-duration test protocol. This finding is in line with  
354 several studies that use ACE (Castro et al. 2010; Smith et al. 2006) as well as leg cycling protocols (Bentley and  
355 McNaughton 2003; Bishop et al. 1998). These studies consistently find that high increments in workload lead to a  
356 higher  $PO_{peak}$ , shorter time until exhaustion but similar  $\dot{V}O_{2peak}$  compared to protocols with lower increments in  
357 workload and longer time until exhaustion. The differences in  $PO_{peak}$  despite a similar  $\dot{V}O_{2peak}$  in the shorter  
358 protocols are likely due to more anaerobic energy contribution, which is a consequence of reaching higher PO's  
359 sooner in the shorter protocols, hence an earlier recruitment of higher order motor units and an earlier transition to  
360 anaerobic metabolism. This is further supported by the higher RER and a trend towards a higher  $\dot{V}CO_2$  during the  
361 shorter and moderate duration compared to the longer duration protocols in the current study. In the longer duration  
362 test protocol, the TWD (kJ) until  $PO_{peak}$  was 135% and 54-57% higher compared to the short and moderate test  
363 protocols, respectively. This likely caused a greater accumulation of localised muscular fatigue and as a result a  
364 lower  $PO_{peak}$  in the test protocol of longer duration. Despite the anaerobic indicators,  $\dot{V}CO_{2peak}$  and RER, being  
365 higher in the overall shorter duration protocols, no effect of test protocol on  $bLa_{peak}$  was found. This finding is in  
366 contrast to Smith et al. (2006), where the test protocol with higher workload increments led to a higher  $bLa_{peak}$   
367 compared to the protocol with lower workload increments. Overall, it depends on the outcome parameter of interest  
368 whether the four protocols of different workload and increment duration can be used interchangeably.

369

370 It should be noted that too fast and/or high workload increments may result in short times until exhaustion due to  
371 a rapid onset of muscle fatigue (Scheuermann et al. 2002), which may further lead to not reaching the highest  
372 possible  $\dot{V}O_{2peak}$ . In the present study, similar values for  $\dot{V}O_{2peak}$  were found comparing incremental test protocols  
373 with time until exhaustion in the range of 4 min 32 s to 10 min 45 s. In this context it is important to consider that  
374 the well-trained nature of the participants, which includes a fast cardio-respiratory adaption to an increase in  
375 exercise intensity, in the present study likely influenced the ability to reach  $\dot{V}O_{2peak}$  within the short duration test  
376 protocol. In order to find the upper and lower limits of test protocol duration for attaining  $\dot{V}O_{2peak}$ , future studies  
377 should assess the effects of even shorter and longer duration incremental UBP test protocols. This should also be  
378 specifically addressed in in participants with a disability (i.e. spinal cord injury or an amputation).

379 Furthermore,  $\dot{V}O_{2peak}$  may also be influenced by the criteria used for stopping the  $\dot{V}O_{2peak}$  tests. For example, in  
380 the study by Smith et al. (2006) tests were stopped once participants were not able to maintain a crank-rate at or  
381 above 75 revolutions per minute, whereas the participants in our study were allowed to continue poling despite a  
382 drop in PO as long as  $\dot{V}O_2$  did not plateau or drop. If we had used a drop in PO as stop criteria for the tests in the  
383 present study,  $\dot{V}O_{2peak}$  would have been underestimated by 3.5 mL·kg<sup>-1</sup>·min<sup>-1</sup> in the shorter duration protocol, 2.6  
384 and 3.2 mL·kg<sup>-1</sup>·min<sup>-1</sup> in the moderate duration protocols and 3.4 mL·kg<sup>-1</sup>·min<sup>-1</sup> in the longer duration protocol.  
385 Despite a drop in PO, we observed that  $\dot{V}O_2$  still increased (Figure 2). Speculatively, this might be related to an  
386 increased recruitment of “stabilising” muscles in the trunk and possibly the lower legs. This increased active  
387 muscle mass might contribute to an increase in  $\dot{V}O_2$  towards  $\dot{V}O_{2peak}$  despite not directly contributing to power  
388 production, i.e. making the movement less efficient. Furthermore, it may be associated with a “lag” in  $\dot{V}O_2$   
389 response, where adjustment in cardiac output, VE and arterio-venous O<sub>2</sub> uptake is not instantaneous. Therefore,  
390 the responses in  $\dot{V}O_2$  lag behind the increase in PO, and this lag has been found greater in the higher/shorter

391 increments (Davis et al. 1982) and greater during arm- compared to leg exercise (Koga et al. 1996). These findings  
392 are important to consider when adapting future test protocols with the UBP and other upper-body exercise modes.

393

#### 394 **Conclusion**

395

396 The present study demonstrated that UBP test protocols with different increments in workload and duration in the  
397 range from 20 W/30 s to 10 W/60 s do not influence  $\dot{V}O_{2peak}$ ,  $VE_{peak}$ ,  $HR_{peak}$  and  $bLa_{peak}$ , and may therefore be  
398 used interchangeably when these parameters are of interest. However, the protocols with increments of short  
399 duration and/or high workloads resulted in a higher  $PO_{peak}$ , RER and a shorter time until exhaustion compared to  
400 increments of lower workload and longer duration. Therefore, the protocols cannot be used interchangeably when  
401 the latter parameters are of interest. Furthermore, this study showed that allowing participants to continue poling  
402 despite a drop in PO as long as  $\dot{V}O_2$  do not plateau or drop, leads to a higher  $VO_{2peak}$ . Our results are limited to  
403 upper-body trained male individuals, therefore the extent to which our findings apply when testing athletes with a  
404 disability remains to be investigated.
