Received (in Cambridge, UK) 18th August 1999, Accepted 12th October 1999

The objective of the research was to study the effects of alkylidene bridges on the conformations and the conformational behaviour of overcrowded homomerous bistricyclic aromatic ethenes (1). The isopropylidenebridged bistricyclic ethene **2** and **3** were synthesized by a reductive "dimerization" of **7**, using TiCl₄–Zn–pyridine–THF. The methylene-bridged bistricyclic ethenes **4**–**6** were synthesized by LiAlH₄–AlCl₃–Et₂O reductions of the corresponding bianthrones. The structures of **2**–**6** were established by ¹H- and ¹³C-NMR spectroscopy and in the cases of **2** and **3**, also by X-ray analysis. Compounds **2** and **3** adopted C_i -anti-folded conformations with 53.0° and 28.8° folding dihedrals between pairs of benzene rings of tricyclic moieties. The central $C_9=C_9$, bond in **2** was essentially planar. A short $C_9 \cdots C_{10}$ distance of 2.81 Å in **2** indicated an intramolecular overcrowding effect in the highly folded bistricyclic ethene. Semiempirical PM3 and AM1 calculations of the *anti*-folded, *syn*-folded, twisted and orthogonally twisted conformations of **2** and **4**. indicated that *anti*-folded **2** and **4** were the most stable conformations with folding dihedrals of 48.7° and 45.0°, respectively at AM1. A DNMR spectroscopic study of *E*, *Z*-isomerizations and conformational inversions gave $\Delta G_c^{\dagger}(E = Z) = 99.6$ kJ mol⁻¹ (DBr₃) and $\Delta G_c^{\#}$ (inversion) = 97.9 kJ mol⁻¹ (hexachlorobutadiene) in **5** and ΔG_c^{\ddagger} (inversion) > 108 kJ mol⁻¹ (benzophenone) in **3**. These high energy barriers were interpreted in terms of less overcrowded fjord regions in the *anti*-folded ground-state conformations.

Introduction

Bistricyclic aromatic enes (1) have served as attractive sub-

strates for the study of the conformations and dynamic stereochemistry of overcrowded ethenes.¹⁻³ Several of these systems, *e.g.*, bianthrone (1, X = Y: C=O) and dixanthylene (1, X = Y: O), display thermochromic, photochromic and piezochromic properties.³ The bistricyclic enes are nonplanar due to the intramolecular overcrowding in their fjord regions.³ The nonplanarity introduces the notion of chirality to the arena of these interesting compounds.⁴ Two principal modes of out-ofplane deviation were considered: twisting around the central carbon-carbon double bond and out-of-plane bending.⁵ In 1, the bending is realized by folding of the tricyclic moieties at both ends of the central ene about the $C_9 \cdots X$ and $C_{9'} \cdots Y$ axes, resulting in boat conformations of the central rings. In addition, the atoms C_9 and $C_{9'}$ may be pyramidalized. Four pure conformations of 1 were considered: the twisted (t), the anti-folded (a), the syn-folded (s) and the orthogonally twisted (\mathbf{t}_{\perp}) conformations (Fig. 1).³ Homomerous bistricyclic enes (1,

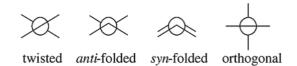

Fig. 1 Schematic projection along $C_9=C_{9'}$ of various types of conformations of bistricyclic enes (lines represent the peripheral benzene rings of the tricyclic moieties).

X = Y) with five-membered and six-membered central rings adopt twisted conformations (t) and *anti*-folded (a) conformations, respectively.³

Bistricyclic enes may undergo the following fundamental dynamic processes:³

- 1. *E*,*Z*-isomerization (*e.g.*, $\mathbf{t}_E \stackrel{\longrightarrow}{=} \mathbf{t}_Z, \mathbf{a}_E \stackrel{\longrightarrow}{=} \mathbf{a}_Z$),
- 2. Conformational inversion, *e.g.*, inversion of the helicity in the twisted 1 $(t_P = t_M)$ or inversion of the boat conformation in the central rings of folded 1,
- 3. *syn, anti*-isomerization (**a**→**s**), *anti*, twisted-isomerization (**a**→**t**) and *syn*, twisted-isomerization (**s**→**t**).
- Enantiomerization and racemization may also be considered in these processes.

The dynamic stereochemistry of bistricyclic enes 1 with central six-membered rings have been studied by Agranat *et al.*, and by Feringa *et al.*, using dynamic NMR (DNMR) and equilibration techniques, when one of the conformational isomers is available in a pure form.³⁻⁹ The DNMR studies revealed low barriers for thermal *E,Z*-isomerization ($\Delta G_c^{\dagger} = 75-115$ kJ mol⁻¹).^{3,6-10} The range of free energies of activation for thermal conformational inversion of bistricyclic enes with central sixmembered rings was found to be similar. These remarkably low energy barriers were interpreted predominantly in terms of ground state destabilization due to steric strain and overcrowding.³ It has been shown that the barriers depend on the bridges

X and Y, on the C–X and C–Y bond lengths, and on the $\rm C_{4a}-C_{10a}$ distances. 6

The present article describes the syntheses, molecular and crystal structures, semiempirical calculations and DNMR study of homomerous bistricyclic enes with methylene and isopropylidene bridges (1, X = Y: CH_2 and 1, X = Y: CMe_2). In these systems, the $\rm C_{sp^2}\!-\!C_{sp^3}$ bonds at the bridges ($\rm C_{4a}\!-\!C_{10}$ and C_{10} - C_{10a}) are expected to be longer than the corresponding $\rm C_{4a}{-}X$ and $\rm C_{4a}{-}Y$ in dixant hylene, $\it N, N'$ -dimethylbiac ridan and bianthrone.³ The alkylidene-bridged 1 are thus expected to possess a higher degree of folding and to be less overcrowded in the fjord regions. Furthermore, the methylene and isopropylidene bridges contain axial and equatorial hydrogen atoms and methyl groups in the boat-shaped central six-membered rings, which in principle allow a determination of the inversion barriers of the parent bistricyclic enes. Heteromerous bistricyclic enes with one CMe2 bridge have previously been studied.11

Synthesis

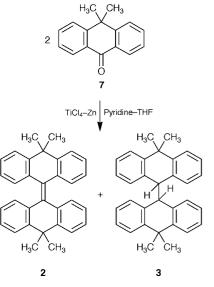

The following compounds were synthesized: 10-[10,10-dimethyl-9(10*H*)-anthracenylidene]-9,10-dihydro-9,9-dimethyl-anthracene (2), 10-[10,10-dimethyl-9(10*H*)-anthracenyl]-9,10-

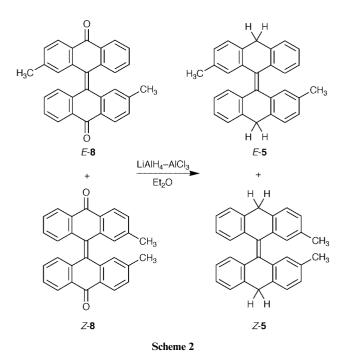

dihydro-9,9-dimethylanthracene (3), 9-[9(10H)-anthracenylidene]-9,10-dihydroanthracene (4), 9-[2-methyl-9(10H)anthracenylidene]-9,10-dihydro-2-methylanthracene (5) and 5-[3-methyl-5(12H)-naphthacenylidene]-5,12-dihydro-3-methylnaphthacene (6). The synthesis of 2 was accomplished by a low-valent titanium-induced reductive "dimerization" of 10,10dimethylanthracen-9(10H)-one (7) using the Mukaiyama-Lenoir procedure¹²⁻¹⁴ of the McMurry reaction¹⁵ (TiCl₄-Znpyridine-THF) (Scheme 1). The reaction afforded a 1:3 mixture of 2 and 3 in 66% yield. The products were separated and purified by recrystallizations. Hydrocarbon 2 has been prepared by a reductive "dimerization" of 7, using zinc in AcOH-HCl.¹⁶ Hydrocarbon 3 has been prepared by hydrogenation of 2, using sodium in pentan-1-ol.16

Compounds **4–6** were synthesized by $LiAlH_4$ -AlCl₃ reduction of bianthrone, 2,2'-dimethylbianthrone and 12-[3-methyl-12-oxo-5(12*H*)-naphthacenylidene]-2-methylnaphthacen-

5(12H)-one, respectively. The synthesis of **4** by a LiAlH₄ reduction of bianthrone¹⁷ and by a reductive "dimerization" of anthrone using aluminium in CH₃CN under the irradiation of ultrasonic wave¹⁸ has been reported. Compounds **5** and **6** were obtained as mixtures of *E*- and *Z*-diastereomers. The synthesis

of (E)-5 and (Z)-5 is depicted in Scheme 2. The structures of 2-6 were established by NMR spectroscopy and elemental analysis. It is possible to distinguish qualitatively among the twisted, syn-folded and anti-folded conformations of homomerous bistricyclic enes (1, X = Y) in solution, using ¹H-NMR spectroscopy. In the cases of 2 and 4, the fjord region protons appear at 7.010 and 6.984 ppm, respectively, indicating that these hydrocarbons adopt anti-folded conformations in solution.^{3,8} A similar picture appears in 5 and 6. In the case of 4, complete assignments were made through two-dimensional correlation spectroscopy (COSY, HSOC, HMBC, NOESY). In the ¹H-NMR spectrum of 4, the methylene protons appear as an AB system at 4.240 and 3.865 ppm. The doublet at 4.240 ppm representing one of the protons of each methylene group was broad, while the second doublet at 3.865 ppm representing the other proton of each methylene group was sharp. In the aromatic region, the double doublet at 7.365 ppm representing H₄, H₅, H_{4'}, H_{5'} was also broad. A COSY experiment indicated an allylic coupling between the 7.365 ppm doublet and the 4.240 ppm doublet. A NOESY experiment indicated through space interactions between the 7.365 ppm doublet and the 3.865 ppm doublet. On the basis of these experiments, it is concluded

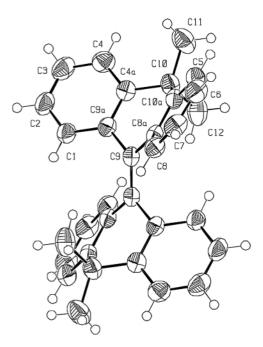

Fig. 2 An ORTEP drawing of 2 derived from the X-ray crystal structure.

that the 3.865 ppm doublet is due to the *equatorial* H_{10eq} while the 4.240 ppm doublet is due to the *axial* H_{10ax} .

Molecular and crystal structures§

Compounds 2 and 3 crystallized in the space group $P2_1/c$.¹⁹ Fig. 2 gives an ORTEP diagram of one molecule of 2 as determined by X-ray analysis. Table 1 gives the conformations and selected geometrical parameters of 2–4 derived from the crystal structures and from semiempirical calculations (*vide infra*).

The molecular and crystal structures of 2 show that the molecule adopts a C_i -anti-folded conformation (a-2). The folding dihedral angle (between the least-squares-planes of the two benzene rings of each tricyclic moiety) of 2 is 53.0°. For comparison, the degree of folding of a metalo-based (PdCl₂ bridge) bistricyclic ene with the 9,9-dimethyl-9,10-dihydroanthra-cenylidene moiety is 48.8°.¹¹ The degree of overcrowding in the fjord regions of 2, as reflected in the intramolecular distances $C_1 \cdots C_{1'}, C_1 \cdots H_{1'}$, and $H_1 \cdots H_{1'}$ is hardly significant: 3.13, 2.97 and 3.11 Å, respectively. For comparison, the van der Waals radii of carbon and hydrogen are 1.71 and 1.15 Å, resulting in van der Waals C · · · C, C · · · H and H · · · H contact distances of 3.42 Å, 2.86 and 2.30 Å, respectively.20 The above $C_1 \cdots C_{1'}$ distance in 2 reflects only an 8% penetration, while the above $C_1 \cdots H_{1'}$ and $H_1 \cdots H_{1'}$ distances do not indicate any penetration. On the other hand, the transannular $C_9 \cdots C_{10}$ distance, 2.81 Å is considerably shorter than the $C \cdots C$, van der Waals contact distance, reflecting an 18% penetration. These short distances indicate an additional effect of intramolecular overcrowding in highly folded bistricyclic enes.

In the previously reported structures of *anti*-folded homomerous bistricyclic enes, pyramidal $C_9=C_9$, carbon atoms have been noted. However, the central carbon–carbon double bond in **2** is essentially planar, with negligible values of the pyramidalization angles χ_9 and χ_9 ,³ and a pure twist of zero.³ The $C_9=C_9$ bond length is 1.347 Å. The relatively long $C_{4a}=C_{10}$ bonds at the bridges, 1.534/1.531 Å, probably enhance the degree of folding. Overcrowding is also evident in the short contact distances between a methyl hydrogen and the corresponding *peri*-hydrogens (H₄, H₅): 2.16 Å.

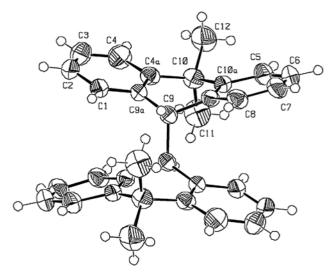

Fig. 3 An ORTEP drawing of 3 derived from the X-ray crystal structure.

Fig. 3 gives an ORTEP diagram of **3** as determined by X-ray analysis. The molecular and crystal structure of **3** show that the molecule adopts a C₁-anti-folded conformation. The folding dihedral angle (A–B, C–D) is 28.8°. The length of the central C₉–C₉, is 1.587 Å. There is a certain degree of overcrowding: the C₁···C₁, and C₉···C₁₀ distances are 3.07 and 2.97 Å, respectively. The short H₄····H₃C distance, 2.04 Å should also be noted.

Semiempirical calculations

Recently, a systematic theoretical survey of overcrowded homomerous and heteromerous bistricyclic enes 1 has been carried out, using MOPAC 6.00 and the semiempirical method PM3.³ The methylene- and isopropylidene-bridged bistricyclic enes 4 and 2 have been included, *inter alia*, in the modelling.³ The present article reports the results of the PM3²¹ and AM1²² calculations of **4** and **2**, using MOPAC 93.²³ Comparisons of AM1 with PM3 have been commented on.^{24,25} The following conformations of 2 and 4 have been considered: C_{2h} -antifolded-2 (a-2), C2v-syn-folded-2 (s-2), C2-syn-folded-2 (C2-s-2), D_2 -twisted-2 (t-2), C_2 -twisted-2 (C_2 -t-2), D_{2d} -orthogonally twisted-2 (t_{\perp} -2), and the corresponding conformations of 4, a-4, s-4, t-4 and t_{\perp} -4. The various conformations have been fully optimized (Keywords: EF SYMMETRY PRECISE GNORM = 0.1 LET DDMIN = 0.0; for orthogonal conformations BIRADICAL was added) and their vibrational frequencies calculated (Keywords: FORCE PRECISE SYMMETRY; for orthogonal conformations BIRADICAL was added). The following conformations were found to be bona fide minima (positive vibrational frequencies): C_{2h} -a-2, C_2 -s-2, C_2 -t-2, C_{2h} -a-4, C_{2v} -s-4 at PM3, C_{2h} -a-2, C_2 -s-2, D_2 -t-2, C_{2h} -a-4, C_{2v} -s-4 at AM1. The following conformations were found to be transition states (one imaginary frequency): C_{2v} -s-2, D_2 -t-4 and D_{2d} -t₁-4 at PM3, D_{2d} - t_{\perp} -2, D_2 -t-4 and D_{2d} - t_{\perp} -4 at AM1. On the other hand, D_2 -t-2 at PM3 and C_{2v} -s-2 at AM1 were found to be second order saddle points. Surprisingly, D_{2d} - t_{\perp} -2 at PM3 was found to be a third order saddle point.

The semiempirical enthalpies of formation (ΔH_f°) of the conformations of 2 and 4, the conformational energies $(\Delta \Delta H_f^{\circ})$ of 2 and 4 (relative to the respective *anti*-folded global minimum conformation) and selected geometrical parameters of the conformations of 2 and 4 derived from the PM3 and AM1 calculations are included in Table 1, together with the corresponding geometrical parameters derived from the crystal structures of 2 and 3. The 3D structures of the AM1 optimized s-2 and a-4 are given in Fig. 4 and Fig. 5. The most stable conformations of 2 and 4 are the *anti*-folded conformations a-2 and a-4. Their fold-

saddle point. ^{*c*} H_{9'}^{***}H₃C.

ing dihedrals are 48.7° and 45.0° at AM1, as compared with 53.0° in the crystal structures of **2**. In **a-2**, the $C_{4a}-C_{10}$ bond at the bridge is elongated, 1.517 Å (PM3) and 1.512 (AM1) as compared with **a-4**, 1.496 Å (PM3) and 1.491 Å (AM1).

In **a-2**, severe methyl, *peri*-H interactions are noted: the CH₃...H₄ contact distance is 1.87 Å (PM3) and 2.03 Å (AM1). The short CH₃...C₉ contact distance in **a-2** should also be noted: 2.76 Å (PM3) and 2.57 Å (AM1). These values are only slightly shorter than the van der Waals hydrogen... carbon contact distance (2.86 Å).²⁰ In **a-4**, the C₉...C₁₀ dis-

tance, 2.84 Å (PM3) and 2.82 Å (AM1) reflects considerable penetration of the van der Waals carbon · · · carbon contact distance, 3.42 Å,²⁰ 17% (PM3) and 18% (AM1). The *anti*-folded conformations are only slightly pyramidalized. However, both *syn*-folded conformations are markedly pyramidalized at C₉: 10.6° (PM3) and 9.5° (AM1) in C_{2v}-s-2 and 13.0° (PM3) and 14.9° (AM1) in s-4. The conformational energies of the *syn*folded conformation are 14.0 (PM3) and 39.4 kJ mol⁻¹ (AM1) in C₂-s-2 and 10.6 (PM3) and 29.1 kJ mol⁻¹ (AM1) in s-4. DFT *ab initio* calculations at B3LYP/6-31G*//HF/6-31G* on the

Table 2 Results of the ¹H DNMR studies of 5 and 6

Compound	Solvent	Process	Probe	$\Delta v_{\rm c}[{\rm H_2}]$	$T_{\rm c}/{\rm K}$	$\Delta G_{\rm c}^{\rm *}/{\rm kJ}~{\rm mol}^{-1}$

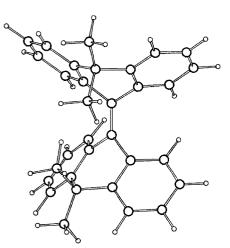

Fig. 4 3D structure of C_2 -s-2 calculated by AM1.

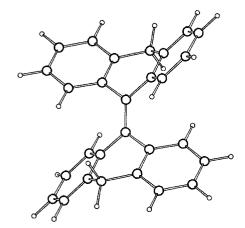

Fig. 5 3D structure of C_{2h} -a-4 calculated by AM1.

related 10,10'-dimethylene derivative of **4** indicated that the *syn*-folded conformation is less stable than the *anti*-folded conformation by 39.1 kJ mol^{-1,26} The *syn*-folded conformations show also short H₁ · · · · H_{1'} contact distances at the fjord regions (1.72 Å (PM3) and 2.04 Å (AM1) in C₂-s-2 and 1.74 Å (PM3) and 1.94 Å (AM1) in s-4). In C₂-s-2, very short CH₃ · · · H₃C distances between the bridges are noted: 1.67 Å (PM3) and 2.07 Å (AM1). The conformational energies of the twisted conformations t-2 and t-4 are practically identical, 63 kJ mol⁻¹ (AM1). The **a**-4→s-4 photoisomerization and a CFF- π electron-CI calculation of s-4 have been reported.^{27,28}

DNMR Spectroscopy

The synthesis of **5** and **6** allowed a DNMR spectroscopic study of the conformational inversions and *E*,*Z*-isomerizations of these methylene-bridged bistricyclic enes. The ¹H-NMR spectrum of **5** included two methyl singlets, indicating the presence of the *E*- and *Z*-diastereomers. In an *anti*-folded conformation of **5**, the symmetries of the *E*- and *Z*-diastereomers are C_i and C_2 respectively; causing both methyl substituents in each diastereomer to be isochronous. The thermal *E*,*Z*-isomerization was studied by monitoring the coalescence of the two methyl signals representing the E- and the Z-diastereomers, respectively. The conformational inversion of 5 and 6 was studied by monitoring the ¹H-NMR coalescence of the AB system representing the diastereotopic axial and equatorial hydrogens of the CH_2 bridges. It should be noted that in 5 and 6, there was not any difference in the chemical shifts of the hydrogens of the CH₂ bridges between the E- and the Z-diastereomers. The results of the DNMR study are summarized in Table 2. In the case of 5, ΔG_c^{\ddagger} ($E \rightleftharpoons Z$) = 99.6 kJ mol⁻¹ (in CDBr₃) and ΔG_{c}^{\ddagger} (inversion) = 97.9 kJ mol⁻¹ (in hexachlorobutadiene). In 6, the corresponding ΔG_c^{\ddagger} values were 100.4 and 96.7 kJ mol⁻¹ (in 1-bromonaphthalene). In the isopropylidene-bridged 2, the ¹H-NMR and ¹³C-NMR spectra led in each case to two separated singlets representing the axial and equatorial methyl groups. Upon a conformational inversion of 2, a $Me_{ax} = Me_{ea}$ interconversion would be expected. A DNMR experiment in naphthalene ($\Delta v = 35$ Hz) up to 207 °C did not show any significant broadening of the two ¹H NMR methyl singlets, indicating that $\Delta G_c^{\ddagger} > 92$ kJ mol⁻¹. Likewise, in benzophenone ($\Delta v = 3$ Hz) at 190 °C, the two methyl ¹H-NMR singlets could still be resolved indicating that $\Delta G_c^{\ddagger} > 108 \text{ kJ mol}^{-1}$. Feringa *et al.* have reported on the conformational inversion of a few cases of heteromerous bistricyclic enes with isopropylidene bridges.⁶ As in the case of 2, a DNMR study of metalo-bridged bistricyclic enes with CMe₂ and ZnCl₂ bridges and with CMe₂ and PdCl₂ bridges did not result in a coalescence of the methyl signals even at 200 °C (in nitrobenzene-d₅).¹¹ The authors suggested that in these cases the results indicated considerable steric hindrance for the isomerization process inverting the folded conformations, and that metal binding results in folded structures completely inert towards interconversions.¹¹ In the case 9-[10,10-dimethyl-9(10H)-anthracenylidene]-2-methyl-9Hof thioxanthene in which the bridges are CMe2 and S, the racemization barrier $\Delta G_{c}^{\ddagger} = 105 \pm 1 \text{ kJ mol}^{-1.6}$

Table 3 gives the free energies of activation for thermal E,Zisomerizations and for thermal conformational inversions of various homomerous bistricyclic enes. The most remarkable result of the present DNMR studies is the relatively high and essentially identical values of the free energies of activation for the E,Z-isomerization and for the conformational inversion. These results are consistent with the mechanisms of the conformational processes of anti-folded bistricyclic enes depicted in Fig. 6 and 7.³ These mechanisms involve a common "edge passage" highest transition state. The higher energy barriers observed in the cases of the methylene-bridged and isopropylidene-bridged bistricyclic enes (e.g., 5 and 2) as compared with dixanthylenes⁸ and bianthrones⁹ are primarily due to the less overcrowded fjord regions in the anti-folded ground states of these systems. The longer C-X bonds in 2, 5 and 6 and the longer $C_{4a} \cdots C_{10a}$ bridge distance allow a higher degree of folding and thus a reduced overcrowding in the fjord regions.⁶ Such an effect is more pronounced in the case of the isopropylidenebridged 2 as compared with the methylene-bridged 4. The significantly higher barrier for the conformational inversion of 2 versus 5 ($\Delta\Delta G_c^{\ddagger} > 8 \text{ kJ mol}^{-1}e$) may also be ascribed to unfavorable steric interactions between one of the methyl groups of 2 and the fjord regions at the opposing ring (e.g., $CH_3 \cdots H_{1'}$) in the transition state, during the "edge passage".

Experimental

Melting points are uncorrected. All NMR spectra were recorded with a Bruker DRX 400 spectrometer, unless otherwise stated. ¹H NMR spectra were recorded at 400.1 MHz using CDCl₃ as solvent and as internal standard (δ (CHCl₃) = 7.26 ppm). ¹³C NMR spectra were recorded at 100.6 MHz using CDCl₃ as solvent and as internal standard (δ (CHCl₃) = 77.01 ppm). The barriers were determined by DNMR spectroscopy, substituting the coalescence temperature T_c and the extrapolated chemical shift difference Δv_c at T_c in the following equation for the Eyring Equation $\Delta G_c^{\dagger} = 4.47 T_c$ [9.97 – log $(T_{\rm c}/\Delta v_{\rm c})].$

10-[10,10-Dimethyl-9(10H)-anthracenylidene]-9,10-dihydro-9,9dimethylanthracene (2) and 10-[10,10-dimethyl-9(10H)-anthracenyl]-9,10-dihydro-9,9-dimethylanthracene (3)²⁹

The reaction was carried out under an argon atmosphere in a 500 mL three-necked round-bottomed flask equipped with a reflux condenser (protected from moisture), a dropping funnel, and a magnetic stirrer. Freshly distilled dry THF (200 mL distilled over sodium diphenyl ketyl) was added to the flask and cooled to -5 °C. Dropwise slow injection of TiCl₄ (1.85 mL, 16.9 mmol) using a plastic syringe with continuous stirring gave a yellow complex, which was treated with Zn dust (2.26 g, 35.5 mmol). The temperature was gradually raised to rt and kept for another 1 h to give a greenish suspension. The mixture was then refluxed for 5 h to complete the reduction,

giving a green-black suspension. After cooling to 0 °C, the mixture was treated with pyridine (2 mL), followed by dropwise addition over 3.5 h of a solution of ketone 7 (3.50 g, 15.5 mmol)²² in dry THF (100 mL). The resulting mixture was refluxed for 48 h. The disappearance of the starting material was monitored by TLC. After being cooled to room temperature, the mixture was added to dichloromethane (300 mL), stirred vigorously and treated with aqueous HCl (0.1 M) to give two layers. The organic layer was separated, and the aqueous layer was extracted with dichloromethane. The organic layers were dried (MgSO₄), and the solvents were removed in vacuum. The crude products (3.0 g) were dissolved in dichloromethane and chromatographed on a silica column, using a hexane-diethyl ether gradient (up to 20% diethyl ether) as eluent. The chromatography afforded 2.1 g (65.6% yield) of the fluorescent yellow products. The ¹H-NMR spectrum (vide infra) indicated a 1:3 mixture of 2 and 3. Recrystallization from benzene gave single crystals of 2 (1:1 complex with benzene), mp 325 °C, suitable for X-ray analysis (lit.,¹⁶ mp 312–313 °C).

Crystal data. Compound 2: Formula $C_{32}H_{28} \cdot C_6H_6$, M =490.69, monoclinic, a = 9.658 (8), b = 15.375 (4), c = 9.975 (2) Å, $\beta = 103.78$ (5)°, V = 1438.6 (9) Å³, rt, space group $P2_1/c$ (no.14), Z = 2, μ (Mo-K α) = 0.32 cm⁻¹, 2306 unique reflections of which 1823 were observed ($I > 2\sigma_I$), R = 0.033, $R_W =$ 0.045.

Compound 3 was isolated from the filtrate of the recrystallization of 2. The solvent was removed in vacuum and the remaining solid was recrystallized three times from dichloromethane. Sublimation at 170 °C/0.1 mmHg gave single crystals of 3, mp 258 °C, suitable for X-ray analysis (lit., ¹⁶ mp 260 °C).

Anal. Calcd for C₃₂H₃₀: C, 92.70; H, 7.30. Found: C, 92.42; H, 6.99%. ¹H-NMR (400 MHz, 363 K, Cl₂CDCDCl₂ δ = 5.15) δ 7.396 (d, ${}^{3}J = 8.0$ Hz, 4H, H₄, H₅, H_{4'}, H_{5'}), 7.179 (t, ${}^{3}J = 7.1$ Hz, 4H, H₃, H₆, H_{3'}, H_{6'}), 6.915 (t, ${}^{3}J = 7.5$ Hz, 4H, H₂, H₇, H_{2'}, H_{7'}), 6.419 (br d, ${}^{3}J = 7.4$ Hz, 4H, H₁, H₈, H_{1'}, H_{8'}), 4.440 (s, 2H, H₉, H_{9'}), 1.562 (s, 6H, CH₃), 0.971 (s, 6H, CH₃). ¹³C-NMR (100 MHz, 363 K, Cl₂CDCDCl₂, δ = 77.007 ppm) δ : 145.71 (C_{4a}, $C_{10a}, C_{4a'}, C_{10a'}$), 135.19 ($C_{8a}, C_{9a}, C_{8a'}, C_{9a'}$), 129.75 ($C_1, C_8, C_{1'}$, C8'), 126.92 (C3, C6, C3', C6'), 126.35 (C4, C5, C4', C5'), 125.27 $\begin{array}{l} (C_2, C_7, C_2', C_7'), 55.78 \ (C_9, C_9'), 38.62 \ (C_{10}, C_{10'}), 33.85 \ (CH_3), \\ 33.64 \ (CH_3). \ MS \ (150\ ^\circ C, \ ^\circ P). \ m/z \ 208 \ (C_{16}H_{16}^{++}, \ 70), \ 207 \ (C_{16}H_{15}^{++}, \ 100), \ 193 \ (C_{15}H_{13}^{++}, \ 71), \ 192 \ (C_{15}H_{12}^{++}, \ 97), \ 191 \end{array}$ $(C_{15}H_{11}^{+*}, 74), 190 (C_{15}H_{10}^{+*}, 26), 189 (C_{15}H_{9}^{+*}, 69), 178 (C_{14}H_{10}^{+*}, 33), 165 (C_{13}H_{9}^{+*}, 49).$

Crystal data. Compound **3**: Formula $C_{32}H_{30}$, M = 414.59, monoclinic, a = 12.139 (4), b = 8.260 (3), c = 11.816 (3) Å, $\beta = 90.97$ (4)°, V = 1184.6 (7) Å³, rt, space group $P2_1/c$ (no.14), Z = 2, μ (Mo-K α) = 0.33 cm⁻¹, 2269 unique reflections of which 1553 were observed ($I > 2\sigma_1$), R = 0.055, $R_W = 0.068$.

9-[2-Methyl-9(10*H*)-anthracenylidene]-9,10-dihydro-2-methylanthracene (5)

The reaction was carried out in an argon atmosphere in a round-bottomed flask equipped with a reflux condenser (protected from moisture) and a magnetic stirrer. Dry diethyl ether (30 ml) was added to the flask followed by anhydrous AlCl₃ (3.6 g, 27 mmol) in small portions and then by LiAlH₄ (0.6 g, 15.8 mmol) in small portions. The mixture was stirred for 30 min at rt, dry benzene (50 ml) was added followed by 2,2'-dimethylbianthrone $(8)^9$ (0.25 g, 0.6 mmol) in small portions. The mixture was then refluxed at 80 °C for 3 h. The excess LiAlH₄ was decomposed by adding dropwise ethyl acetate and the mixture treated by water, followed by dilute aqueous HCl. The organic layer was separated and the aqueous layer extracted with dichloromethane. The combined organic layers were dried (MgSO₄), and the solvents were removed in vacuum. The crude product was purified by preparative chromatography on a PLC silica plate, using benzene as eluent ($R_f = 0.9$). Recrystallization from benzene-petrol ether (40-60 °C) gave 5 as a colorless powder, mp 265–272 °C, in 65% yield. The E: Z ratio was 55:45 (or vice versa).

Anal. Calcd for C₃₀H₂₄: C, 93.70; H, 6.30. Found: C, 93.44; H, 6.08%. ¹H-NMR (400 MHz, CDCl₃, δ = 7.26 ppm) 7.349 (d, ${}^{3}J = 7.5$ Hz, 2H), 7.247 (d, ${}^{3}J = 7.5$ Hz, 2H), 7.076–7.122 (t, ${}^{3}J = 7.4$ Hz, ${}^{4}J = 1.5$ Hz, 2H), 6.912–6.975 (m, 4H), 6.877 (t, ${}^{3}J$ = 7.4 Hz, 2H), 6.787 (br s, 0.45 × 2H), 6.759 (br s, 0.55 × 2H), 4.214 (br d, J = 16.2 Hz, 2H), 3.827 (sd, J = 16.2 Hz, 2H), 2.052 (s, $0.45 \times 6H$ CH₃), 2.037 (s, $0.55 \times 6H$, CH₃). δ (CH₃) $v_E - v_Z$ (270 MHz, CDBr₃, CH₃ signals) 3.75 Hz. Δδ (CH₂, AB system) 100 MHz, hexachlorobutadiene). $v_A - v_B = 41.2$ Hz, $^2J = 16.3$ Hz. DNMR (270 MHz), CDBr₃, $T_c = 4.32 \pm 5$ K, $\Delta v_c = 3.75 \pm$ 0.05 Hz, (CH₃), ΔG_c^{\ddagger} ($E \rightleftharpoons Z$) = 99.6 kJ mol⁻¹. DNMR (100 MHz), hexachlorobutadiene, $T_c = 471 \pm 8$ K, $\Delta v_c = 41.2 \pm 0.5$ (CH₂), ΔG_c^{\ddagger} (inversion) = 97.9 kJ mol⁻¹. MS (% P) *m/z*: $\begin{array}{l} \text{385 (}^{13}\text{C}^{12}\text{C}_{29}\text{H}_{24}^{++}, 32\text{)}, 384 (}^{12}\text{C}_{30}\text{H}_{24}^{++}, 100\text{)}, 383 (}^{12}\text{C}_{30}\text{H}_{23}, \\ \text{26)}, 382 (}^{12}\text{C}_{30}\text{H}_{22}^{++}, 45\text{)}, 192 (}^{12}\text{C}_{30}\text{H}_{24}^{+2}, 73\text{)}. \text{ UV (CH}_2\text{C}_2\text{)} \\ \lambda_{\text{max}} \text{ nm (log ϵ): 253 (4.24), 323 (4.13). }^{13}\text{C-NMR (100 MHz, 100 MHz,$ $CDCl_3$) δ : 139.24, 139.12, 137.90, 137.77, 137.56, 137.39, 135.99, 135.87, 134.14, 133.05, 131.84, 129.63, 129.57, 129.02, 128.93, 127.04, 126.80, 126.65, 126.63, 126.28, 126.26, 124.76, 124.55, 37.15 (C_{10'}, C_{10'}), 37.14 (C_{10'}, C_{10'}), 20.95 (CH₃), 20.85 (CH₃).

9-[9(10H)-Anthracenylidene]-9,10-dihydroanthracene (4)

Hydrocarbon **4** was prepared by a LiAlH₄–AlCl₃ reduction of bianthrone (**1**, X = Y: C=O) analogously to **5** in 50% yield and was obtained after recrystallization from toluene as colorless powder, mp 288–291 °C (decomp.). (Lit.,¹⁷ mp 328 °C).

Anal. Calcd for $C_{28}H_{20}$: C, 94.34; H, 5.66. Found: C, 94.75; H, 5.76%. ¹H-NMR (400 MHz, CDCl₃) δ : 7.364 (dd, ³*J* = 7.5 Hz, 4H, H₄, H₅, H₄', H₅'), 7.117 (dt, ³*J* = 7.4 Hz, ⁴*J* = 1.4 Hz, 4H, H₃, H₆, H₃', H₆'), 6.984 (dd, ³*J* = 7.8, ⁴*J* = 1.0 Hz, 4H, H₁, H₈, H₁', H₈'), 6.894 (dt, ³*J* = 7.5 Hz, ⁴*J* = 1.1 Hz, 4H, H₂, H₇, H₂', H₇'), 4.240 (br d, ²*J* = 16.2 Hz, 2H, CH₂), 3.865 (d, *J* = 15.8 Hz, 2H, CH₂). ¹³C-NMR (100 MHz, CDCl₃) δ 37.60 (CH₂, C₁₀, C₁₀'), 124.83 (C₂, C₇, C₂', C₇'), 126.39 (C₃, C₆, C₃', C₆'), 128.96 (C₁, C₈, C_{1'}, C₈'), 131.97 (C₉, C₉'), 137.70 (C_{8a}, C_{9a}, C_{8a}', C_{9a}'), 139.06 (C_{4a}, C_{10a}, C_{4a'}, C_{10a'}). MS (% P) *m*/*z* 357 (¹³C¹²C₂₇H₂₀^{+*}, 32), 356 (¹²C₂₈H₂₀^{+*}, 100), 355 (¹²C₂₈H₁₉^{+*}, 20), 354 (¹²C₂₈H₁₈, 12), 179 (36), 178 (¹²C₃₀H₂₀⁺², 96). UV (CH₂Cl₂) λ_{max} nm (log ε): 253 (4.34), 320 (4.20).

5-[3-Methyl-5(12*H*)-naphthacenylidene]-5,12-dihydro-3methylnaphthacene (6)

Hydrocarbon **6** was prepared by a LiAlH₄–AlCl₃ reduction of 2-methyl-12-[3-methyl-12-oxo-5(12*H*)-naphthacenylidene]naphthacen-5(12*H*)-one,⁹ analogously to **4**. The product was purified on a silica PLC plate, using dichloromethane–petrol ether (40–60 °C) 1:1 as eluent ($R_{\rm f} = 0.7$). Recrystallization from benzene–petrol ether (40–60 °C) gave **6** as a pale yellowish powder, mp >300 °C (slow decomposition during heating to give a brown–red color). The yield was 72%. The *E*:*Z* ratio was 52:48 (or *vice versa*).

Anal. Calcd for C₃₈H₂₈: C, 94.18; H, 5.82. Found: C, 94.33; H, 5.99%. ¹H-NMR (400 MHz, CDCl₃) δ: 1.834 (s, 0.52 × 6H, $(CH_3)_2$, 2.059 (s, 0.48 × 6H, $(CH_3)_2$), 4.061 (d, ²J = 15.9, 2H, H_{10} , $H_{10'}$), 4.451* (br d, ²J = 16.0, 2H, H_{10} , $H_{10'}$), 6.784 (br s, $0.52 \times 2H$, 6.809 (br s, 0.48 × 2H), 6.914 (d, ${}^{3}J = 7.6, {}^{4}J = 1.0$, 0.52 × 2H), 6.960 (d, ${}^{3}J = 7.5, {}^{4}J = 0.8$, 0.48 × 2H), 7.136 (t, ${}^{3}J = 7.9, {}^{4}J = 1.1, 0.52 \times 2H$), 7.209 (d, ${}^{3}J = 8.1, 0.52 \times 2H$), 7.278–7.346 (m, 5.8H), 7.386 (t, ${}^{3}J = 8.0$, ${}^{3}J = 6.8$, ${}^{4}J = 1.3$, $0.52 \times 2H$), 7.432 (d, J = 8.1 Hz, $0.52 \times 2H$), 7.489 (s, 2H), 7.751 (t, 2H), 7.838 (d, J = 7.9, 2H).
